

# CAPSTONE PROJECT

Neighborhoods in central Mexico City  
By parks availability and quality perception

Spatial analysis- clustering

# INTRODUCTION AND THE PROBLEM

*How are neighborhoods in central Mexico City similar or different to each other based on the availability and quality perception of their public spaces and particularity parks?*

*Can we grouped neighborhoods according to their parks availability and how people rate them?*

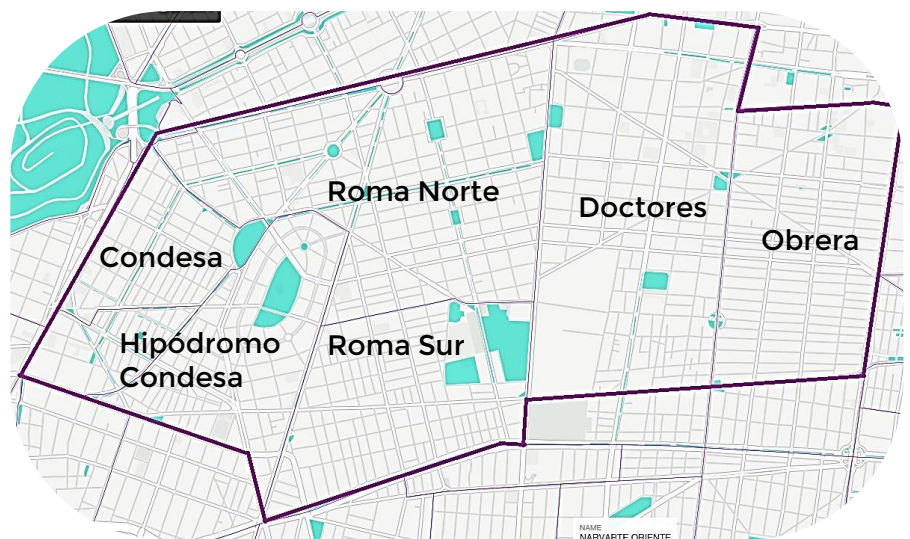

*Are neighborhoods clustered with more and better parks associated with higher level of development and less poverty and the other way around?*

Public spaces such as parks are often unevenly distributed in cities. In some urban areas, usually those with high inequality, there are spatial patterns of concentrations and deficit of public spaces. Some areas might have not only more but also better public spaces than others. There are neighborhoods, on the other hand, that have comparatively few, less vibrant, even unsafe and poor quality public spaces or don't have any at all. This, in some cases, exacerbates, other forms of inequality and deprivation, prevents people to spend time outside and to meet with others. It might also mean they have less access to green spaces, impacting their health and the urban landscape.

Mexico City stands as one of the largest metropolis in the world with about 22 million people and spanning over nearly 8 thousand square kilometers. The city is also full of contrast, with boroughs with a human development index comparable to Finland or France while also some comparable to countries in sub-Saharan Africa. About one third of the population lives in poverty and about 4 percent in extreme poverty, equivalent to 800 thousand people. The city also displays differences within and across boroughs and neighborhoods in terms of infrastructure, services and public spaces,

As shown in the map below, which shows neighborhoods in the central borough Cuauhtemoc and public spaces-parks in green, some neighborhoods in the west have more parks - and are more similar to each other in this regard, while the ones in the east are more similar to each other given their lack of parks. Cuauhtemoc houses about half a million people, areas with high, medium and low development.

Although this is something one could observed by looking a map like the one below and with this overlay, **there is not a tool, analysis or map that groups neighborhoods based on the availability and quality of parks. This prevents understanding this key dimension in the city, guide policy or interventions based on this knowledge and notion. This also would make more difficult for someone to take a decision to move to another neighborhood taking this aspect into consideration.**

# THE GOAL

This project seeks to provide insights into the similarities and differences in neighborhood in central Mexico City (Cuauhtémoc Borough) based on the availability and ratings of parks. It intends to group - cluster the 33 neighborhoods in this borough according to these variables. In addition, it also aims at shedding light into how the resulted grouping is associated with the neighborhood social development.

# THE DATA

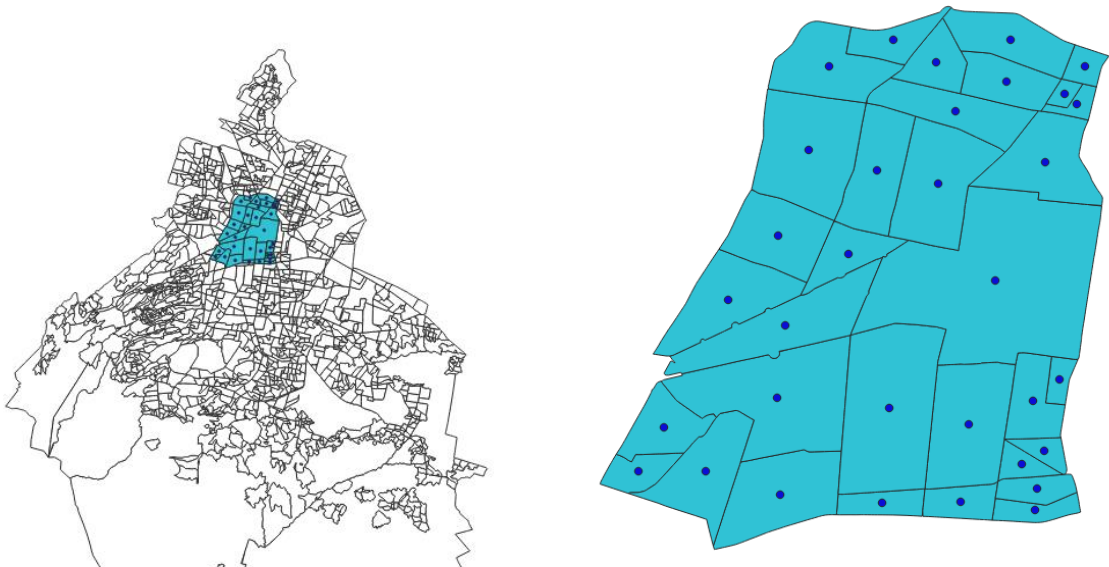

To develop this project data will be used from various sources including foursquare and leveraging the data available through the API.

- 1) The shape files of the Neighborhoods in Mexico City are available for from the city's Urban Development Department. The city has over a thousand neighborhoods distributed in 16 boroughs. For this particular project, only 33 that are part of the Cuauhtemec borough will be filtered and used (highlighted in blue below). I have download the shape files, created new shape and json files with only Cuauhtemec and also generated the centroids of each neighborhoods to have them both as points and polygons.
- 2) Data about the parks location and rating will be gathered using the foursquare API. There is data about 40 parks in Cuauhtemec in a 4km kilometer radius from its centroid coordinates in their data set. Cuauhtemec has about this radius, so this is an appropriate radius. Points that were to be outside the area will be excluded. There is also ratings for the venues in foursquare (see figure in the next page).
- 3) Data on the socio-economic development of neighborhoods is available from the city's social development department (See figure in the next page).

Using data on the parks locations and their ratings, two variables will be created, number of parks and average parks ratings per neighborhood. Each neighborhood in a new data set-frame will have information on these two dimensions. K-means clustering then will be used to group neighborhoods based on these characteristics. The two variables will be normalized to facilitate the method execution. In addition, and once this step is completed, it will be explored what the most common development level of each group using bar plots and spatial overlays of these two dimensions.

# METHODOLOGY

To begin with, data was gathered as explained before using the foursquare API. This was turn into a data frame an into a data set- with the venues of interest and their coordinates.

```
[35]: results = requests.get(url).json()
      results

[35]: {'meta': {'code': 200, 'requestId': '5ef946cc513bb60f5114b60b'},
      'response': {'venues': [{'id': '4cc8ae0b41e75481e20e5884',
                                'name': 'Parque Alameda',
                                'location': {'address': 'Av. Juárez 76',
                                              'crossStreet': 'Esq. con Azueta',
                                              'lat': 19.434515120135995,
                                              'lng': -99.14715262455131,
                                              'labeledLatLngs': [{'label': 'display',
                                                                'lat': 19.434515120135995,
                                                                'lng': -99.14715262455131}],
                                              'distance': 80,
                                              'postalCode': '06010'}
```

```
[39]: venues = results['response']['venues']
      # transform venues into a dataframe
      dataframe = json_normalize(venues)
      dataframe.head(5)
```

After getting the json file from foursquare with the venues of interest, using QGIS, I started by identifying points, venues-parks, that were outside the Cuauhtemoc Area. This is done using the select by location tool The adjacent figure shows in yellow areas that fall within the polygon of interest while the green ones not.

I also created a new shape file with only those points that intersect the Cuauhtemoc area or the yellow points. That is exporting the selected features into a new shape file.

Then, as shown below I also merged the parks layer with the neighborhood layers. This way, each park now has information on the neighborhood in which it is located.

Contar puntos en polígono

The algorithm takes a points layer and a polygon layer and counts the number of points for the first one in each polygon of the second one.

A new polygons layer is generated, with the exact same content as the input polygon layer, but containing an additional field with the point count corresponding to each polygon.

An optional weight field can be used to assign weights to each point. If set, the count generated will be the sum of the weight field for each point contained by the polygon.

Alternatively, a unique class field can be specified. If set, points are classified based on the selected attribute, and if several points with the same attribute value are within the polygon, only one of them is counted. The final count of the point in a polygon is, therefore, the count of different classes that are found in it.

Both the weight field and unique class field cannot be specified. If they are, the weight field will take precedence and the unique class field will be ignored.

By generating the new data set with the number of parks per neighborhood it is already possible to see visualize this variable. In the adjacent map it is possible to see the parks (the green dots) and the polygons according the number of parks they have. Centro has 9 parks, while some other neighborhoods have 2 or 1, while the majority has none.

Then, for each of the 23 parks I went back to the foursquare Api to find their rating.

```

I created a new data frame CNPD which stand for Cuauhtemoc Neighborhood parks data, with the normalized number of parks and the normalized average rating of parks for each neighborhood.

And then I ran k-means clustering to identify neighborhoods clusters based on these two variables.

And then I ran k-means clustering to identify neighborhoods clusters based on these two variables.

```

# RESULTS

The project first allow to identify the number of parks in each neighborhood and how they were rated. It was possible to visualize neighborhoods according to the availability and perceived quality -rating of parks. Centro was the neighborhood with the largest number of parks: 9 . Then there were also three neighborhoods with two parks, and eight neighborhoods with one park. Also, it was found that there were 21 neighborhoods with no parks at all, most of which, are located in the south east and northern parts of the city. In addition, while centro has the highest number of parks, the highest average rating of parks are in Condesa and Hipodromo. These are among the richest neighborhoods in Cuauhtemoc and the city.

# RESULTS

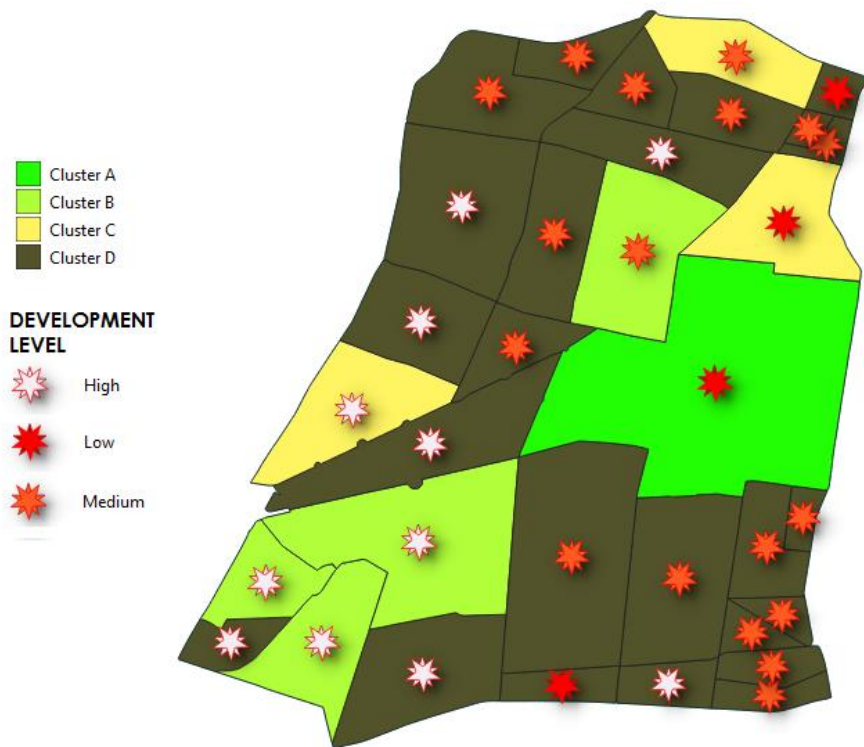

The project allow to cluster neighborhoods based on both availability and rating of parks. Centro stands alone in cluster A, as it houses nearly half of all parks in Cuauhtemoc, but not necessarily the best rated ones. In cluster B are found neighborhoods characterized by few parks but highly rated parks. Most are found in the western part of the city, in Condesa, Hipodromo and Roma Norte. Cluster C is characterized by few and badly rated parks while cluster D is comprised by neighborhoods by no parks at all.

The map below shows each cluster by different color dots. It also shows in the right and corner with the same color ramp the whole neighborhood polygons according the cluster they belong to.

# RESULTS

The map below shows in an overlay neighborhood polygons according their cluster and the development level with dot stars. Although parks are found in areas with low development as Centro in cluster 1, and in areas with medium development as well, high development areas coincide with cluster B, which is characterized by few but good parks. Nonetheless, some high development areas are also found in cluster D which is characterized by having no parks. All we can say is that neighborhoods in cluster B, with few but highly rated parks, are mainly areas with high development, but not the other way around.

This research has contributed to the understanding on how neighborhoods in central Mexico City, the Cuauhtemoc borough, are similar to each other based on the availability and quality perception- rating of parks. It was that there is uneven provision of parks, with nearly two thirds of neighborhoods having no parks. The latter was one of the characteristics of one of the 4 clusters generated, cluster D. Cluster A, was mainly Centro, which was characterized by a large number of parks but not necessarily the highest rated ones. Cluster B on the other hand, was characterized by few but good - high rated parks. Cluster C was characterized by few and not so good parks according to how people rated them.

There are and there are not parks in low, medium and high development neighborhoods. However, cluster B, which again, was characterized by the best parks according to people, are mainly high development areas. Condesa, Roma Norte and Hipodromo, which are among the richest neighborhoods not only in Cuauhtemoc, but the city and even the country, are similar in terms of their availability and quality of parks, they have few but the ones people consider the best.

It is recommended that parks not only be available for neighborhoods in cluster D, in particular in areas such as Buenos Aires, which has no parks and has low development but also to improve those in cluster A and B so that they might be as good as in cluster B.

# DISCUSSION Y CONCLUSIONS

This research has contributed to the understanding on how neighborhoods in central Mexico City, the Cuauhtemoc borough, are similar to each other based on the availability and quality perception- rating of parks. It was that there is uneven provision of parks, with nearly two thirds of neighborhoods having no parks. The latter was one of the characteristics of one of the 4 clusters generated, cluster D. Cluster A, was mainly Centro, which was characterized by a large number of parks but not necessarily the highest rated ones. Cluster B on the other hand, was characterized by few but good - high rated parks. Cluster C was characterized by few and not so good parks according to how people rated them.

There are and there are not parks in low, medium and high development neighborhoods. However, cluster B, which again, was characterized by the best parks according to people, are mainly high development areas. Condesa, Roma Norte and Hipodromo, which are among the richest neighborhoods not only in Cuauhtemoc, but the city and even the country, are similar in terms of their availability and quality of parks, they have few but the ones people consider the best.

It is recommended that parks not only be available for neighborhoods in cluster D, in particular in areas such as Buenos Aires, which has no parks and has low development but also to improve those in cluster A and B so that they might be as good as in cluster B.
